A B S T R A C T

The antioxidant 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO) group was covalently introduced into polydicyclopentadiene (PDCPD) through ring-opening metathesis polymerization (ROMP) copolymerization of dicyclopentadiene (DCPD) with a TEMPO-derived norbornene comonomer. The thermal oxidation of the resulting thin films was monitored by ThermoGravimetric Analyses (TGA) and Fourier-Transform Infra-Red spectroscopy (FT-IR). This new PDCPD stabilized by immobilization of the TEMPO antioxidant shows a better thermo-oxidative stability at 60 °C under air than an industrial formulation of PDCPD stabilized with 2,6-di-tert–butyl–4-methylphenol (BHT). Impact of thermal oxidation on mechanical behaviour of both formulations have been studied by tensile tests and fracture tests, based on the essential work of fracture (EWF) concept. The TEMPO-functionalized PDCPD offers a promising alternative to BHT-stabilized PDCPD with comparable ductility but slower decay and better cracking resistance, confirming the benefit of the TEMPO antioxidant in PDCPD formulation when chemically bound to the matrix.

1. Introduction

Polydicyclopentadiene (PDCPD) is one of the most industrially manufactured polymers by ring-opening metathesis polymerization (ROMP) of dicyclopentadiene (DCPD) \cite{1}, which is produced in large quantities as a byproduct of petroleum cracking \cite{2-4} (Scheme 1). This thermoset polymer processed by reaction injection moulding (RIM) is extensively crosslinked \cite{5} and displays particularly interesting physical and chemical properties, i.e., a very high impact resistance coupled with a good resistance to chemical corrosion and a high heat deflection temperature \cite{6,7}. These properties have been exploited for manufacturing of impact-resistant and tough moulded parts used in automotive industry to produce body panels, bumpers, and other components for trucks, buses and tractors \cite{8-10}. However, compared with other hydrocarbon polymers, the high concentration in remaining double bonds in PDCPD and a high catalyst residues concentration used for the ROMP of DCPD enhances the sensitivity to oxidation compared to other hydrocarbon polymers \cite{11}, limiting its use in severe environments such as the marine environment for deep-sea oil extraction \cite{12}.

PDCPD is usually stabilized by adding 2,6-di-tert–butyl–4-methylphenol (BHT) to the DCPD formulation, which offers high inhibition efficiency and low cost \cite{13-15}. However, the effectiveness of such low-molar mass additive is limited by incompatibility \cite{16} and migration out polymer matrix \cite{17-18}. Despite the presence of BHT, PDCPD undergoes oxidation that favors crosslinking leading to a large increase in glass transition temperature ($T_g$) together with an increase in rubbery modulus and maximal stress \cite{19} and, as a consequence, an embrittlement of the polymer. Use of the hindered amine light stabilizer (HALS) stabilizer Tinuvin 123 or Chimassorb 2020 instead of BHT allows to improve the protection performance especially when lowering the ageing temperature \cite{20}.

Approaches that can dramatically improve polyolefin thermo-oxidative stability have been developed by chemically binding antioxidant groups along the polymer chain. The addressed synthetic strategies are based on (i) post-polymerization modification (PPM) \cite{21-23}, and (ii) copolymerization of an antioxidant-containing comonomer with olefin or vinyl monomers \cite{24-26}. This latter
approach is the most suitable one for PDCPD, according to its crosslinked nature.

The copolymerization of DCPD with a functionalized norbornene-based monomer has been already reported to access low density polymeric aerogels [27], metal-cation-based anion exchange membranes [28,29], as self-healing agents in microcapsules [30], and films [31].

In our group, we have studied the copolymerization of DCPD with an hindered phenol-containing norbornene (Scheme 2A). Thermal ageing of the resulting resin has shown an induction period while virgin PDCPD oxidized instantly [32]. Furthermore, we have for the first time shown the efficiency of 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO)-containing dicarboximide norbornenes as stabilizing agents in polypropylene [33].

Considering these encouraging results, this study details preparation of TEMPO-functionalized PDCPD materials by bulk copolymerization between DCPD and a nitroxide radical-containing norbornene (Scheme 2B) followed by examination of their thermal ageing behaviour. Finally, impact of the thermal ageing on the mechanical properties of TEMPO-functionalized PDCPD materials have been investigated, and compared to those of a BHT-stabilized PDCPD.

2. Experimental section

2.1. Materials

2,6-Di-tert-butyl-4-methylphenol (BHT, ≥ 99%, Sigma-Aldrich), dicyclopentadiene (DCPD, TELENE SAS), and ruthenium salicylaldimine phenylindenylidene complex (TELENE SAS), were used as received. Exo-5-norbornene-2,3-dicarboximido-N-TEMPO)butanamide (NB-TEMPO) was synthesized according to a literature procedure [33].

2.1.1. General procedure for preparation of PDCPD films

In a typical experiment, stabilized bulk PDCPD materials were prepared in a 100 mL plastic beaker by mixing 10 g of DCPD and the desired quantity of BHT or nitroxide radical-containing norbornene (1.044 mmole/100 g of DCPD). 0.1 g of a solution of the ruthenium salicylaldimine phenylindenylidene complex provided by TELENE SAS was then added to the mixture. The polymerization occurs immediately at room temperature in 10 min. After polymerization, material was cut in 15–25 µm slices using a Reichert Jung microtome. Samples were stored at −20°C before ageing for a maximum of a week.

2.1.2. Thermo-oxidative ageing

Samples were subjected to thermo-oxidative ageing in air-circulating ovens at atmospheric pressure at 60°C and 90°C.

2.2. General characterization

ThermoGravimetric Analyses (TGA) were performed on a TA Instruments Q500 apparatus and the testing conditions were as follows: the chamber was purged at 30°C by nitrogen at a flow rate of 90 mL.min⁻¹ for 5 min and the sample was then heated at a heating rate of 10°C.min⁻¹ to 120°C under pure oxygen flow rate of 90 mL min⁻¹.

Fourier Transform Infra-Red (FT-IR) spectra were obtained using a Nicolet avatar 370 DTGS system. Spectra were obtained at regular time intervals in the MIR region of 4000–500 cm⁻¹ at a resolution of 4 cm⁻¹ (640 scans) and analysed using OPUS software.

Tensile tests were carried out using an Instron tensile machine. Experiments were performed using 60 µm thick samples in order to obtain homogeneous oxidation through the sample thickness. Samples were cut in a dog-bone shape with an initial working length of 10 mm. They were tested after several ageing durations using an Instron test machine with a 50 N load cell. Tests were performed at 2 mm.min⁻¹ and strain measured by Digital Image Correlation. The reported values are the average ±1 standard deviation of at least eight measurements.

Essential Work of Fracture (EWF) measurements were performed on an InstronTM test machine with a 50 N load cell, in double notched tensile mode, with a loading rate of 2 mm.min⁻¹. Samples were 60 mm thick with a width of 10 mm. They were notched on each side using a scalpel, the distance between the
3. Results

3.1. Preparation of stabilized DCPD films

Stabilized bulk DCPD materials were obtained by bulk copolymerization between DCPD and the nitroxide radical-containing norbornene (NB-TEMPO, Scheme 3) used both as comonomer and stabilizing agent using a ruthenium salicylaldimine phenylindenylidene complex as the initiator. The concentration of the stabilizing agent has been set at the same concentration as in the industrial formulation (see experimental section) when 2,6-di-tert-butyl-4-methylphenol (BHT) is used, i.e. 1.044 mmol in phenol function per 100 g of DCPD. Indeed, previous studies have shown that the use of more stabilizing agent in DCPD does not improve its efficiency [20]. For comparison, incorporation of antioxidant in the DCPD formulation has then been performed by bulk polymerization of DCPD in the presence of the commercially available stabilizing agent: hindered phenol BHT (Scheme 3).

3.2. Stabilized DCPD films thermo-oxidation

The effect of stabilizers was evaluated by accelerated ageing tests. For that purpose, a BHT-stabilized bulk DCPD (DCPD-BHT) film, a purified DCPD film, i.e. a DCPD-BHT film from which the antioxidants have been removed by extraction according to a literature procedure [37], and a NB-TEMPO-stabilized bulk DCPD (PDCPD-NB-TEMPO) film were in situ aged in ThermoGravimetric Analyses (TGA) apparatus under pure oxygen flow at 120 °C. During ageing, thermal oxidation has been shown to occur according to the following process [38]. Allylic radicals are generated by the abstraction of hydrogen from the allylic C-H of the DCPD (labelled a, b and c in Schema 4A) by radical species. These allylic radicals react with oxygen to give peroxo radicals POO⁻. These in turn abstract a hydrogen from another allylic C-H to form hydroperoxides POOH (Scheme 4B). They then undergo decomposi-
tion by a unimolecular or bimolecular mechanism [39], leading to alkoxy PO' radicals, which rearrange into unsaturated ketones, with or without cleavage of the vicinal C–C bond, or to alcohols (Scheme 4C). Thermal oxidation of PDCPD thus leads to a progressive increase in the mass of the film, which is monitored by TGA.

As observed in Fig. 1A, kinetic curves for mass increase display the classical behaviour with an induction period followed by an auto-acceleration stage classical for the oxidation of hydrocarbon polymers. As previously described [37], induction period for purified PDCPD is almost close to 0, due to the relatively high instability of this polymer at the considered temperature. This induction period is significantly increased (Fig. 1B) by adding the stabilizing agent usually used in industrial PDCPD formulations: hindered phenol BHT.

The replacement of free stabilizer BHT by the covalently bounded NB-TEMPO in PDCPD films with the same concentration in active groups allows to increase the induction period (Fig. 1C), demonstrating the greater efficiency of the TEMPO stabilizing agent. This implies (i) that the TEMPO group displays a better radical trapping capacity and/or (ii) that the BHT migration out of the polymer limits its antioxidant behaviour. The greater efficiency of mobile (non-grafted) hindered amine stabilizers compared to BHT to stabilize PDCPD supports the second hypothesis [20]. The thermal ageing of these films at 60 °C and 90 °C has also been monitored by Fourier Transform Infra-Red (FT-IR) spectroscopy by converting carbonyl absorbances appearing at 1650–1750 cm⁻¹ (stretch vibration mode of C=O) into concentrations using Beer-Lambert's law with ε₀ = 300 L.mol⁻¹.cm⁻¹ [40] (Fig. 2).

The results confirm the higher efficiency of amine-based stabilizers compared to hindered phenols.

3.3. Impact of the thermal ageing on the mechanical properties of stabilized PDCPD films

Fig. 3 presents typical stress/strain curves obtained during uniaxial tensile test for PDCPD-BHT and P(DCPD-NB-TEMPO) 60 μm thick dog-bone specimens in order to obtain homogeneous oxidation through the sample thickness. Let us first focus on unaged P(DCPD-NB-TEMPO) material (black curve, Fig. 3A), a linear portion is first observed corresponding to an elastic behaviour. Then, at a stress close to 22 MPa, a yield occurs where plastic deformation takes place within the polymer. Finally, an elongation at break can be measured, about 20% for the unaged samples. In presence of BHT (black curve, Fig. 3B), the mechanical behaviour of PDCPD-BHT is the same except that maximal stress is about 30 MPa suggesting a higher crosslink density in this material before ageing. During ageing, the same behaviour is observed for both materials, i.e. a decrease in elongation at break as well as an increase in maximal stress and finally a complete embrittlement for PDCPD-BHT (after 120 h at 60 °C). The most interesting point here is the fact that even after 408 h at 60 °C, P(DCPD-NB-TEMPO) is not brittle whereas PDCPD-BHT is brittle after 120 h. These results confirm improvement of the PDCPD durability already observed by FT-IR spectroscopy and mass changes using nitroxide radical-containing norbornene both as stabilizer and comonomer.

As shown in a previous study [19], determination of fracture properties in PDCPD can be achieved using DENT (double edge notched specimen) samples through the Essential Work of Fracture specially to understand the decrease in strain at break.

At the unaged state, the energy necessary to propagate a crack in P(DCPD-NB-TEMPO) is lower than for PDCPD-BHT. Here again, this behaviour could be due to a lower crosslink density in the polymer. During ageing, a clear decrease in βWp (i.e. the slope in Fig. 4B) is observed for PDCPD-BHT during oxidation at 60 °C. When this value is equal to 0 then it means that the polymer is brittle. On the contrary, for P(DCPD-NB-TEMPO), there is no large impact of thermal oxidation on the βWp even after 120 h at 60 °C.

**Fig. 1.** Kinetics of mass uptake at 120 °C under pure oxygen flow for (A) purified PDCPD, (B) PDCPD-BHT, and (C) P(DCPD-NB-TEMPO) films.

![Fig. 2](image2.png)

**Fig. 2.** Carbonyls concentration-time profiles during ageing under air of PDCPD-BHT and P(DCPD-NB-TEMPO) films at (A) 60 °C and (B) 90 °C.
As a conclusion on the study of the impact of thermal oxidation on mechanical properties of two PDCPD stabilized with the usually used BHT in industrial PDCPD formulations and the nitroxide radical-containing norborne n NB-TEMPO used both as comonomer and stabilizing agent, it appears that the consequences of oxidation are the same for the two polymers, i.e. an embrittlement of the material. However, with both tensile tests and fracture tests, the embrittlement time is much longer for P(DCPD-NB-TEMPO) (more than 400 h vs 120 h with PDCPD-BHT at 60 °C). These results confirm the benefit of using the new stabilizer developed in this study.

4. Conclusion

A new antioxidant moiety was chemically bound to a PDCPD matrix by bulk copolymerization between DCPD and a TEMPO-containing norborne. The thermal oxidation of resulting thin films studied by TGA at 120 °C in pure oxygen shows an improved stability with an increase of the period induction compared with thin films of BHT-stabilized PDCPD which was confirmed by kinetics of carbonyl concentration built up monitored by FT-IR for ageing at 60 and 90 °C under air. While the consequences of oxidation of the BHT-stabilized PDCPD and TEMPO-functionalized PDCPD formulations on their mechanical properties both lead to an embrittlement of the material, this embrittlement occurs for this latter after an improved latency of a factor of 3. The opportunity to immobilize an antioxidant to the PDCPD matrix gives a new perspective for use in severe environments such as the marine environment for deep-sea oil extraction.
